

Linear Least Square

- Often we have more equations than unknowns, because, for example, some experiments have been repeated several time,
- We obtain different results because of different input data.
- These results are arranged by more equations m than unknowns n . The transformation A has dimensions $m \times n$. Columns of A span n -dimensional vector space.
- Resulting system $Ax=b$ is solved in the best way if the residual $r=b-Ax$ is minimal, so the best fitting x to the existing data b is obtained.

University of Salzburg, Department of Scientific Computing, CMDIE WS 2003/04

1

Linear Transformations

- A linear transformation A in general changes the length and the direction of a vector x .
- Some special transformations are often needed that preserve vector norms - orthogonal transformations.
- A solution is the best possible, if the residual is minimal, that is, if it is orthogonal (perpendicular) to the column space of A .
- So we have to solve least squares problem by a smaller square system but triangular matrix has to be obtained by an orthogonal transformation that will preserve the solution.

University of Salzburg, Department of Scientific Computing, CMDIE WS 2003/04

2

Housholder Transformation

Norm is preserved by reflection.

University of Salzburg, Department of Scientific Computing, CMDIE WS 2003/04

3

Housholder QR Factorization

```

for j=1:n % for each column j
    n=norm(A(j:m,j)) % column norm
    v=A(j:m,j)-n*e_j % vector v
    for i=j:n %update all unfactorized
        for k=j:m % column entries
            A(k,i)=A(k,i)-(2*(v'*A(k,i))/(v'*v))*v;
        end
    end
end
end
    
```

We must update b also, transforming the system $A^*x=b$ in $R^*x=Q^T*b(1:n)$

Complexity: $O(n^2m-n^3/3)$

University of Salzburg, Department of Scientific Computing, CMDIE WS 2003/04

4

Givens Rotation

- Rotation,
- Norm preserved.

$$\text{norm}(a)=\sqrt{a_1^2+a_2^2}=5.39$$

$$c=a_1/\text{norm}(a)=0.37$$

$$s=a_2/\text{norm}(a)=0.93$$

$$G=[c \ s; -s \ c]=[.37 \ .93; -.93 \ .37]$$

$$Ga=[5.39, 0]$$

University of Salzburg, Department of Scientific Computing, CMDIE WS 2003/04

5

Givens QR Factorization

```

for j=1:n % for each column j
    for k=m:-1:j+1 % from bottom
        c=A(k-1,j)/sqrt(A(k,j)); % c
        s=A(k,j)/sqrt(A(k,j)); % s
        G(k-1,k-1)=c; Gi(k,k)=c;
        G(k,k-1)=-s; Gi(k-1,k)=s;
        A=G*A; %update matrix A
    end
end
    
```

We must update b also, transforming the system $A^*x=b$ in $R^*x=Q^T*b(1:n)$

Complexity: $O(n^2m-n^3/2)$ (50% more than Householder)

University of Salzburg, Department of Scientific Computing, CMDIE WS 2003/04

6

Grahm-Schmidt Orthogonalization

- Orthogonalization,
- Norm preserved.

University of Salzburg, Department of Scientific Computing, CMDIE WS 2003/04

7

Modified Gram-Schmidt QR Factorization

```

R=zeros(m,n) % place for R
for k=1:n % for each column k of A
    R(k,k)=norm(A(:,k)); % column norm
    A(:,k)= A(:,k)/ R(k,k) % normalize
    for j=k+1:n % for all unfactor.colu.
        R(k,j)=A(:,k)*A(:,j) % orthogonalize
        A(:,j)=A(:,j)-R(k,j)*A(:,k) % update
    end
end
    
```

Extra space is needed for R!

We must update b also, transforming the system $A*x=b$ in $R*x=Q^T*b$

Complexity: $O(n^2m-n^3)$

University of Salzburg, Department of Scientific Computing, CMDIE WS 2003/04

8

Total Least Squares

$$f(t,x)=xt \quad \begin{array}{l|l} t & -2 & -1 & 3 \\ y & -1 & 3 & -2 \end{array}$$

Ordinary Least Square

$[t]*x = [y]$
vertical distances

Total Least Square

$[y]*x = [t]$
horizontal distances

$[t,y]=U\Sigma V^T \quad x=-v_{1,2}/v_{2,2}$
perpendicular distances

University of Salzburg, Department of Scientific Computing, CMDIE WS 2003/04
